Back End Assessment

Objective

Build a simple **Money Tracker API** using **PHP Laravel**. This is a **backend-only** assessment. An existing frontend application will consume your API endpoints.

The system should allow users to manage multiple wallets (accounts). For example, a user may have different wallets for different businesses.

When viewing a user's profile, one should be able to get:

- All wallets belonging to the user
- The balance of each wallet
- The user's overall balance

When viewing a specific wallet, one should be able to get:

- The wallet's balance
- All transactions for that wallet

Functional Requirements	**Technical Requirements**

Users should be able to:
1. Create a user account (no authentication required)
2. Create one or more wallets
3. Add transactions to a wallet:
  ○ Income
  ○ Expense
4. View their profile, which includes:
  ○ All wallets
  ○ Each wallet's balance
  ○ Total balance across all wallets
5. Select a single wallet to view, which includes:
  ○ Wallet balance
  ○ All transactions for that wallet
	Please ensure the following:
	• Create appropriate models
	• Set up proper database relationships and migrations
	• Implement basic controllers (at minimum store and show methods)
	• Define API routes
	• Add basic validation (Required fields, Positive amounts, Valid transaction type)
	• Ensure balances are calculated correctly:
	  ○ Income adds to balance
	  ○ Expense subtracts from balance
	• Write clean, readable, well-structured code with appropriate comments
	• Make multiple, descriptive commits (preferably one commit per feature)
	Example commit messages:
	• "Created user and wallet migrations"
	• "Added wallet controller"
	• "Implemented transaction validation

Submission Instructions

Share a link to your public Git repository for review. Please ensure your commit history clearly shows your development progress.
